

## A NEW SPECIES OF ORIGANUM (LABIATAE) FROM LIBYA

J. H. IETSWAART

Vakgroep Plantensystematiek, Biologisch Laboratorium, Vrije Universiteit, Amsterdam

### SUMMARY

A new species of *Origanum*, *O. akhdarensis*, is described from GEBEL AKHDAR (Cyrenaica, Libya) and its position in the genus is briefly discussed.

### *Origanum akhdarensis* IETSWAART et BOULOS\* sp. nov., Fig. 1.

Species haec affinis *O. cyrenaeicum* Beg. et Vacc. sed foliis tenuioribus puberulis pallide virentibus, bracteis parvioribus margine ciliatis, labiis inferioribus calycum manifeste bidentatis labia superia aequilongis, corollis purpureis diversa.

Fruticulus, flores bisexuales. *Surculi juveniles* puberuli. *Caules* basi lignosi et sparsim ramosi, erecti vel adscendentes, c. 30 cm alti, pallide brunei, puberuli. *Rami spiciferi* in parte superiori caulis, c. 7 pares per caulem, 6 (2-14) mm longi; ramuli spiciferi brevissimi in ramis inferioribus interdum praesentes. *Folia* c. 14 pares per caulem, puberula (pro parte pilis capitatis); petioli c. 1,5 mm longi; laminae subrotundatae vel ovales, apice obtuso, 16 (8-19) mm longae, 13 (6-16) mm latae, tenues, pallide virentes, margine paulum ciliatae (pilis c. 1 mm longis), glandibus sessilibus obsoletis, usque ad 150 per cm<sup>2</sup>. *Spicae ellipsoideae*, c. 12 mm longae, c. 6 mm latae, plus minusve nutantes. *Bracteae* c. 7 pares per spicam, oblongae, apice plus minusve acuto, c. 6 mm longae, c. 2 mm latae, pro parte pallide purpurascentes, indumento fere ut in foliis. *Flores* 2 per verticillastrum, subsessiles. *Calyces* pro 1/5 parte bilabiati, c. 5 mm longi, extus puberuli, margine ciliati, faucibus annulo villosu; labia superiora integra (vel brevissime dentata); labia inferiora longitudine superiora aequantia, in dentes duos triangulares, c. 1 mm longos, tota divisa. *Corollae* pro 1/4 parte bilabiatae, c. 11 mm longae purpureae, non saccatae, fere glabrae; labia superiora pro c. 1/8 parte in lobos duos aequilongos obtusos, c. 0,3 mm longos, divisa; labia inferiora superioribus paulo longiora, pro c. 3/4 parte in lobos tres paulum inaequilongos ovales, c. 1,7 mm longos, divisa. *Stamina recta*, longe exserta; filamenta usque ad 6 mm et 8 mm longa. *Styli* usque ad 16 mm longi. *Nucae* c. 1 mm longa.

\* Professor Dr. L. BOULOS collected the specimens of this new species in 1970. His address is: Department of Biological Sciences, University of Jordan, Amman, Jordan.

Fig. 1. *Origanum akhdarensis* Ietswaart et Boulos sp. nov.: (a) stem, (b) leaf, (c) bract, (d) calyx, view of upper lip, (e) calyx, view of lower lip, (f) calyx cut between the two lower lip teeth, (g) flower with bract, (h) corolla cut through middle lobe of lower lip.

Libya, Cyrenaica, GEBEL AKHDAR, WADI EL-KOUF, 27 Oct. 1970, *L. Boulos* no. 4469 (holotype in CAI, isotype in AVU).

*Origanum akhdarensis* is the second species of the genus found in Cyrenaica. The other one, *O. cyrenicum*, has been described by BÉGUINOT & VACCARI (1913) and is mentioned in the *Prodromus della Flora Cirenaica* by PAMPANINI (1931). Both species are endemic for Cyrenaica and are rather closely related. They have the following characters in common: a chamaephytic habit, frequent occurrence of non-flowering axillary sprouts in the lower part of the stems, short spike bearing branches that persist after the bracts and flowers have fallen off, small bracts that are only slightly purple coloured and an entire (or nearly entire) calyx upper lip. The two species are, however, distinctly separated by several other characters. In *O. cyrenicum* the leaves are more or less hirsute and leathery, the bracts measure c. 7 × 4 mm and are not ciliate, the lower lip of the calyx measures c. 1/6 of the upper lip length and is slightly bidentate, and the corolla is white.

In *O. akhdarensis* the leaves are minutely pubescent, thin and not leathery, the bracts measure c. 6 × 2 mm and are ciliate at the margin, the lower lip of the calyx is as long as the upper lip and is clearly bidentate, and the corolla is purple coloured. On account of characters in calyx and flower-spike both species should be attributed to the group *Amaracus* within the genus *Origanum*. They lack some of the features that mark the greater part of the species in this group, however, like: large, conspicuous purple coloured, clearly nodding flower spikes and stamens ascending under the upper lip.

#### ACKNOWLEDGEMENTS

The author is indebted to Dr. M. VROMAN for his critical reading of the manuscript and his valuable suggestions, to Drs. A. J. DOP and Drs. D. C. IETSWAART for correction of respectively the English and Latin text.
